

Ideas:

1. Rail track inspection or road inspection device, gets added to car/railway cart
2. SmokeScout is a small, cheap autonomous robot that firefighters send into a burning building before they enter themselves. It stays low where the smoke is thinnest and uses thermal imaging and radar instead of a camera, sending out a live map with occupant locations while the crew is still outside. Existing fire robots are either water cannons or need someone driving them with a remote — ours needs no operator, is cheap enough to abandon, and gets more accurate every call as firefighters report back what they actually found.
3. HandBook is a sealed box with a hand crank, a battery, and a small computer running a language model entirely offline — you crank for under a minute, ask it a question, and it answers with no network and no grid power. It exists because after a hurricane or in a remote area the power and the network are the first things to go, and a phone is dead within two days. The project's real question, and its headline result, is one nobody has published: **how much usable knowledge can you buy per joule of human effort** — a bigger model knows more but costs more cranking, and the tradeoff curve between accuracy and joules is what we measure.
4. Smart fridge
5. Rizz glasses
6. HUD
7. Smart referee band
